

in their development than the Lamellibranchiata. Even among the terrestrial and aquatic Pulmonata there are striking differences. Some of the Pectinibranchiata are remarkable for the curious cases in which their eggs are hatched and the young developed, to an advanced state of growth. The cases of Pyrula and Strombus are among the most extraordinary of these organic nests. The embryology of Cephalopods¹ has been masterly illustrated by Kölliker.

There is still much diversity of opinion among naturalists, respecting the limits of Articulata; some being inclined to separate the Arthropoda and Worms as dis-

Ueber verschiedene Formen von Seethieren, Müller's Arch., 1854, p. 69.—Ueber Synapta digitata und über die Erzeugung von Schnecken in Holothurien, Berlin, 1852, 4to. fig.—The remarkable case described in this paper, admits of an explanation which Müller has not considered. It is known, that fishes penetrate into the cavity of the body of Holothuriae, through its posterior opening. (DE BOSSER, Notice, etc., Mém. Soc. Sc. Nat., Neuch., 1839, vol. 2, 4to.) The similarity of Entoconcha mirabilis with the embryonic shell of various species of Littorina, such as Lacuna vincta, the development of which I had an opportunity of studying, suggests the possibility, that some species of this family, of which there are many very small ones, select the Synapta as their breeding place and leave it after depositing their eggs, which may become connected with the Synapta, as our Mistletoe or the Orobanche and many other parasitic plants, with the plants upon which they grow.—GEGENBAUER, (C.)
